

# Introduction to R

Session 5 – Advanced Graphics

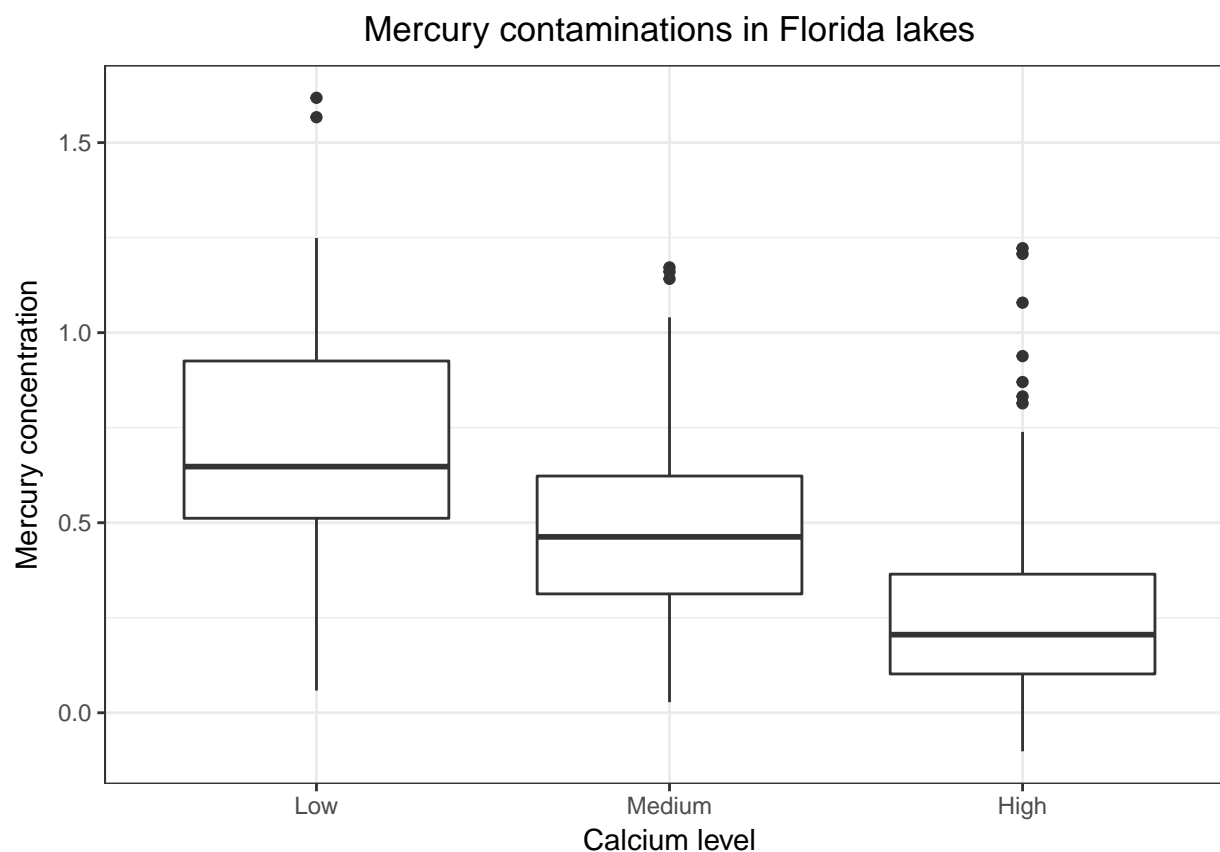

*Statistical Consulting Centre*

*20 July, 2017*

## 1. Boxplot

1. Draw boxplots showing the distribution of Mercury for each of the levels of Calcium. The boxplot should look exactly like

```
ggplot(joined.long.df, aes(Calcium, Mercury)) +  
  geom_boxplot()+  
  labs(title = "Mercury contaminations in Florida lakes",  
        x = "Calcium level", y = "Mercury concentration") +  
  theme_bw() +  
  theme(plot.title = element_text(hjust = 0.5))
```

## 2. Scatterplot

Draw a scatter plot which shows the relationship between pH and Mercury for each of the Calcium levels. The scatter plot should look exactly the same as

```
ggplot(joined.long.df, aes(x = pH, y = Mercury,
                           col = Calcium, shape = Calcium)) +
  geom_point() +
  labs(title = "Mercury contaminations in Florida lakes",
       x = "pH value", y = "Mercury concentration") +
  theme_bw() +
  theme(plot.title = element_text(hjust = 0.5))
```

## 3. Barplot

Draw a juxtaposed barplot that shows the average Mercury concentration for the six combinations of Calcium and pHtype. The graph should look exactly the same as

```
joined.long.df %>%
  group_by(Calcium, pHtype) %>%
  summarise(Mean = mean(Mercury)) %>%
  ggplot(aes(x = Calcium, y = Mean,
             fill = pHtype)) +
  geom_col(position = "dodge") +
  labs(x = "Calcium level", y = "Mean Mercury concentration")
```

#### 4. Heatmap

```
ggplot(joined.long.df, aes(x = pHtype, y = Calcium)) +  
  geom_tile(aes(fill = Mercury)) +  
  scale_fill_gradient(low = "red", high = "green") +  
  theme_bw()
```
